# A Blockchain-Enabled Multi-Controller SDN-based Resilient Networking Management Mechanism

The University of Akron  
College of Engineering

# Outline

- Background & Motivations
- Our Proposed Networking Solution with Case Studies
  - Integrity Verification Mechanism
  - Autonomous Malicious-Host Detection Mechanism
  - Autonomous Bandwidth Provisioning Mechanism
- Conclusions

# Background & Motivations

- Software-Defined Networking (SDN) is a promising technology

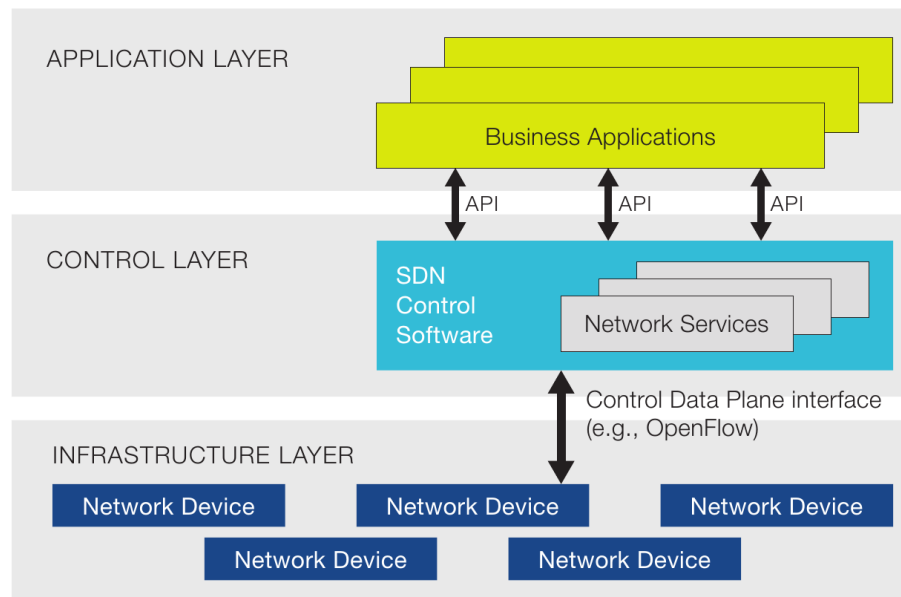

Fig.1: An example SDN architecture (source: <https://www.opennetworking.org/images/stories/downloads/white-papers/wp-sdn-newnorm.pdf>)

# Background & Motivations

- There still remain essential challenges of implementing SDN such as the scalability and security of the control plane

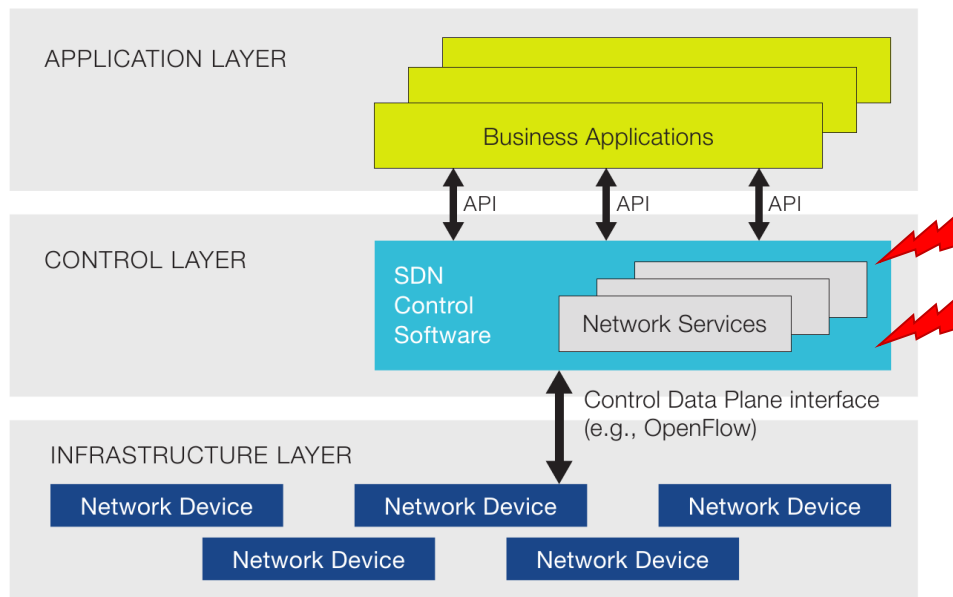

Fig.2: An example SDN architecture with attacks on SDN controller.

# Background & Motivations

- We develop a blockchain-enabled multi-controller SDN-based resilient networking management mechanism.

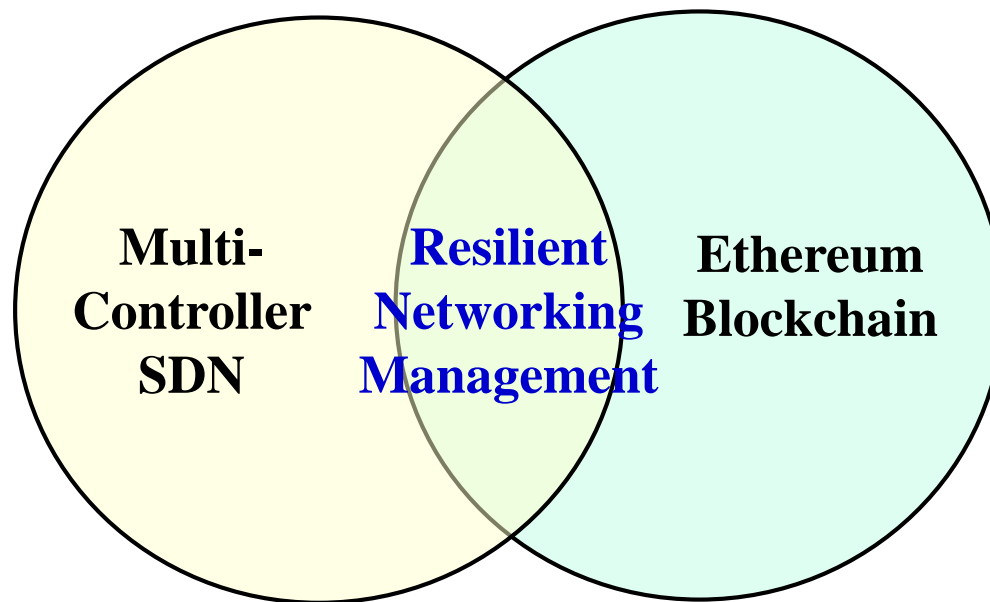

Fig.3: The overview of our proposed mechanism

# Background & Motivations

## Structure of Creating and Adding New Blocks

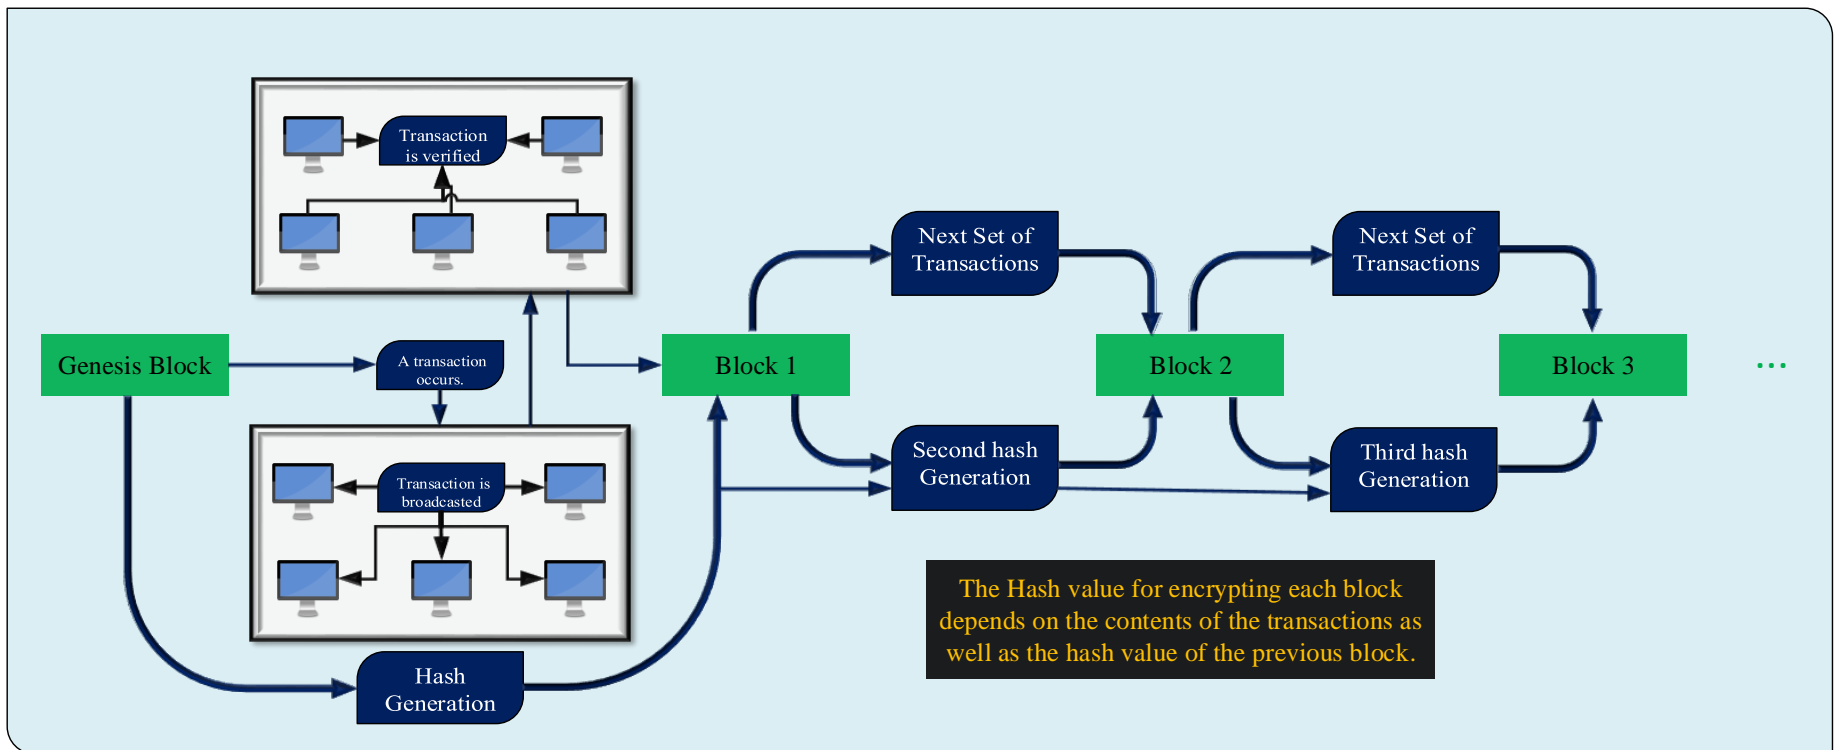

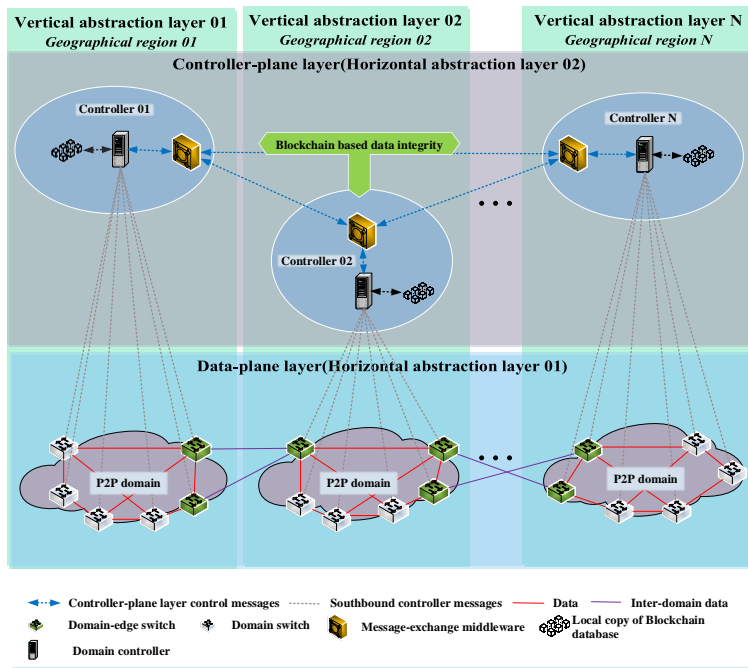

Fig.4: Illustration for blockchain technology.

# Our Proposed Networking Solution with Case Studies

- When considering a mission which spans across multiple geographical regions, we are developing a blockchain-powered multi-controller SDN-based networking architecture.

- There will be two horizontal abstraction layers in this architecture. The bottom layer will be the data-plane layer while the top layer will be the controller-plane layer.
- Vertical abstraction layer is divided into several clusters where each cluster is controlled by a dedicated controller.

Fig.5: High-level overview of our blockchain-powered multi-controller SDN-based networking interface.

# Our Proposed Networking Solution with Case Studies

## Integrity Verification Mechanism

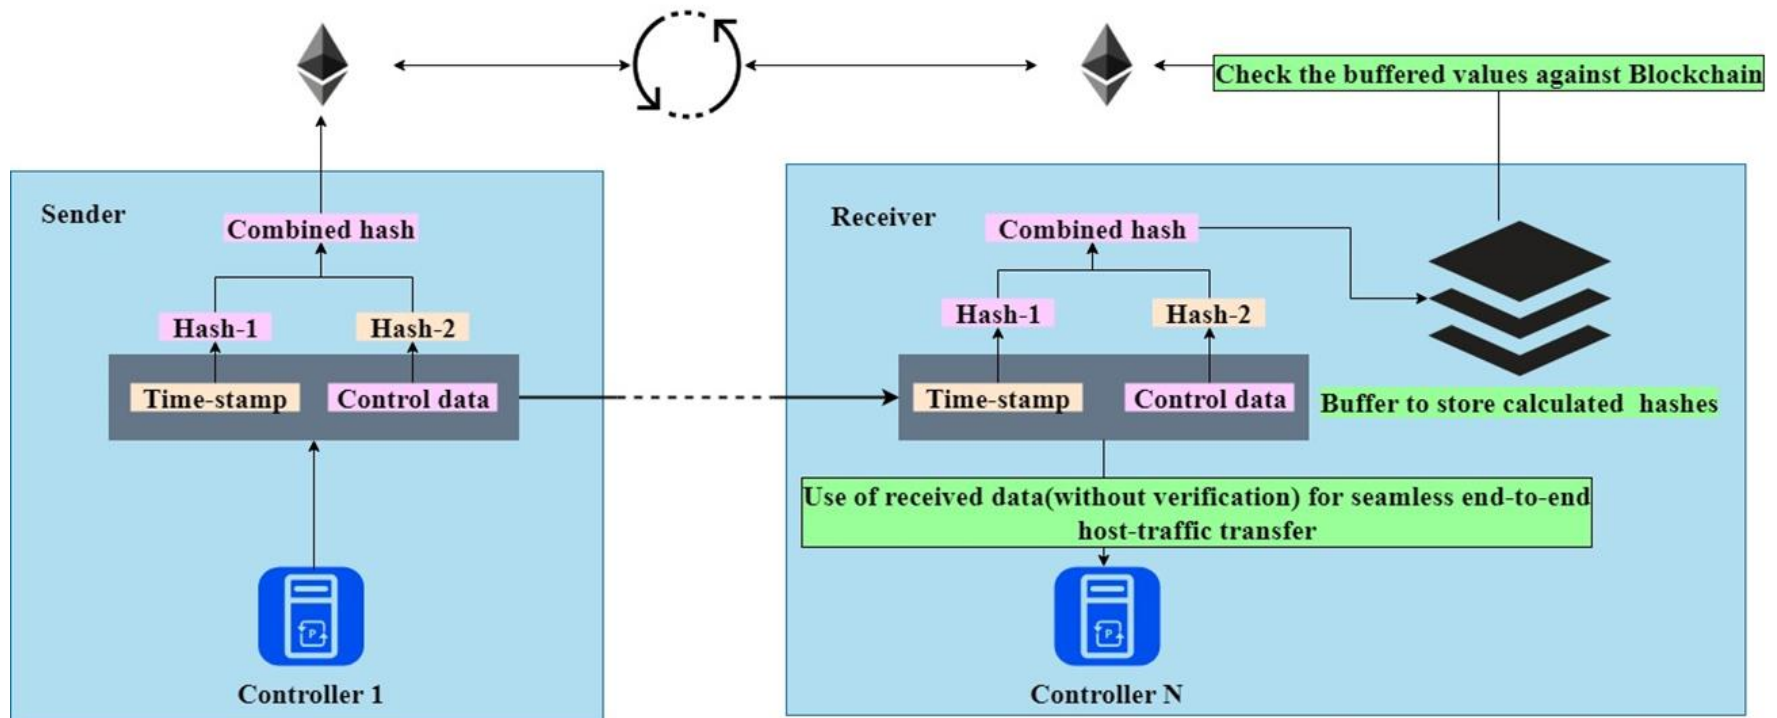

Fig.6: Illustration of securing the integrity of controller-controller communications.

# Integrity Verification Mechanism

## Case Studies

- We implemented a simple multi-controller topology in which:
  - There are three Controllers C0, C1 and C2 that can communicate with each other via exchanging ARP messages.
  - The three associated SDN domains are connected with each other via domain-edge Switches s5, s10 and s11 that are used for inter-domain traffic.
  - The integrity of ARP requests and responses received by a controller is guaranteed by leveraging the functionality of Ethereum blockchain.

Fig.7: Network topology.

# Case Studies

- Verifying the validity by pinging from known host to a known destination by a ping from Host 1 at C1 to Host 2 at C0.
  - We assume that neither the C1 nor C0 knows about the MAC address of each other.
  - Initially, C1 floods an ARP request, requesting the MAC address of C0 throughout all the domains, where the request will be propagated to C0 and C2.

Fig.8: Network topology with dataphath.

# Case Studies

- Verifying the validity by pinging from known host to a known destination by a ping from Host 1 at C1 to Host 2 at C0.
  - When C1 sends the ARP request to other controllers, it also hashes the ARP request and uploads it to the blockchain.
  - The following screenshot shows the corresponding console output of C1.

The screenshot displays a terminal window with console output from controller C1. Two lines of output are highlighted with red boxes and red arrows pointing to labels on the right. The first line is "Flooding initial ARP request throughout all domains", which is labeled "Flooding of the ARP request". The second line is "Appending [bf4977a47f7dc4bc03dcd7998058ac64] to blockchain array...!!!", which is labeled "Hashing of the ARP request and adding it to blockchain". Other visible output includes "INFO:requests.packages.urllib3.connectionpool:Starting new HTTP connection (1): 127.0.0.1" and "INFO:requests.packages.urllib3.connectionpool:Starting new HTTP connection (2): 127.0.0.1 Handling IP packet between 10.0.0.1 and 10.0.0.2".

```
Flooding initial ARP request throughout all domains
INFO:requests.packages.urllib3.connectionpool:Starting new HTTP connection (1): 127.0.0.1
Appending [bf4977a47f7dc4bc03dcd7998058ac64] to blockchain array...!!!
INFO:requests.packages.urllib3.connectionpool:Starting new HTTP connection (2): 127.0.0.1
Handling IP packet between 10.0.0.1 and 10.0.0.2
```

# Case Studies

- The ARP request are received by both C0 and C2. Upon reception, they will check the validity of the received ARP requests by hashing them and cross validating the hashes against the blockchain.
- Following console outputs of C0 and C2 show the cross validation of the received ARP request, respectively.

```
packet is destined from domain : 2 to domain: 1 | This is domain 3 | Hence packet is discarded...  
Handling IP packet between 10.0.0.2 and 10.0.0.1
```

```
packet is destined from domain : 1 to domain: 2 | This is domain 3 | Hence packet is discarded...
```

```
[bf4977a47f7dc4bc03dcd7998058ac64] was verified in 16.6654291153 seconds
```

Cross validation of the received ARP request

```
Handling ARP packet: 10.0.0.2 requests the MAC of 10.0.0.1
```

```
Sending the ARP reply to : 10.0.0.2
```

```
[bf4977a47f7dc4bc03dcd7998058ac64] was verified in 16.6561820507 seconds
```

Cross validation of the received ARP request

# Case Studies

- After the ARP requests have been properly flooded, host 2 at C0 will send the ARP reply to host 1 at C1. After crafting the ARP reply, the controller will upload the hash of the reply to the blockchain.

Appending [03d7de0e6879ac27598642c35564f10d] to blockchain array...!!!

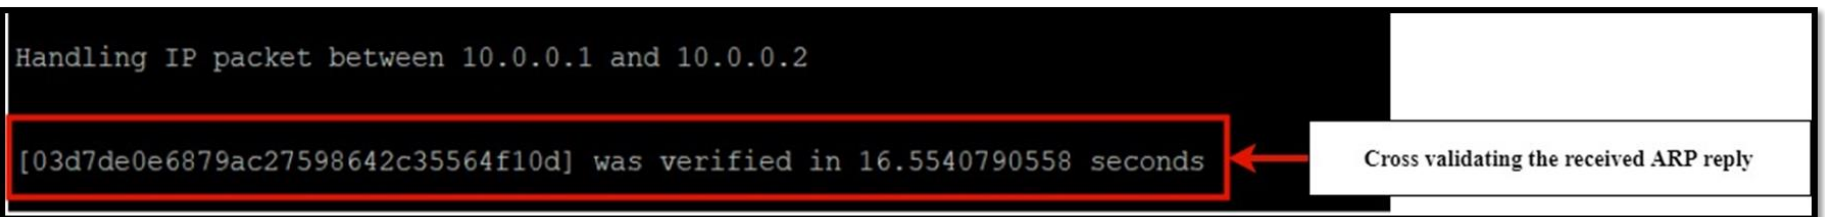

Handling IP packet between 10.0.0.1 and 10.0.0.2

Handling IP packet between 10.0.0.2 and 10.0.0.1

Uploading the ARP reply to the blockchain

The screenshot shows a terminal window with a black background and white text. The first line is highlighted with a red box and has a red arrow pointing to it from a white box on the right that says "Uploading the ARP reply to the blockchain". Below this, there are two lines of text: "Handling IP packet between 10.0.0.1 and 10.0.0.2" and "Handling IP packet between 10.0.0.2 and 10.0.0.1".

- Upon the reception of the ARP reply, the destination controller, C1, verifies the hash of the received ARP reply against the blockchain.

Handling IP packet between 10.0.0.1 and 10.0.0.2

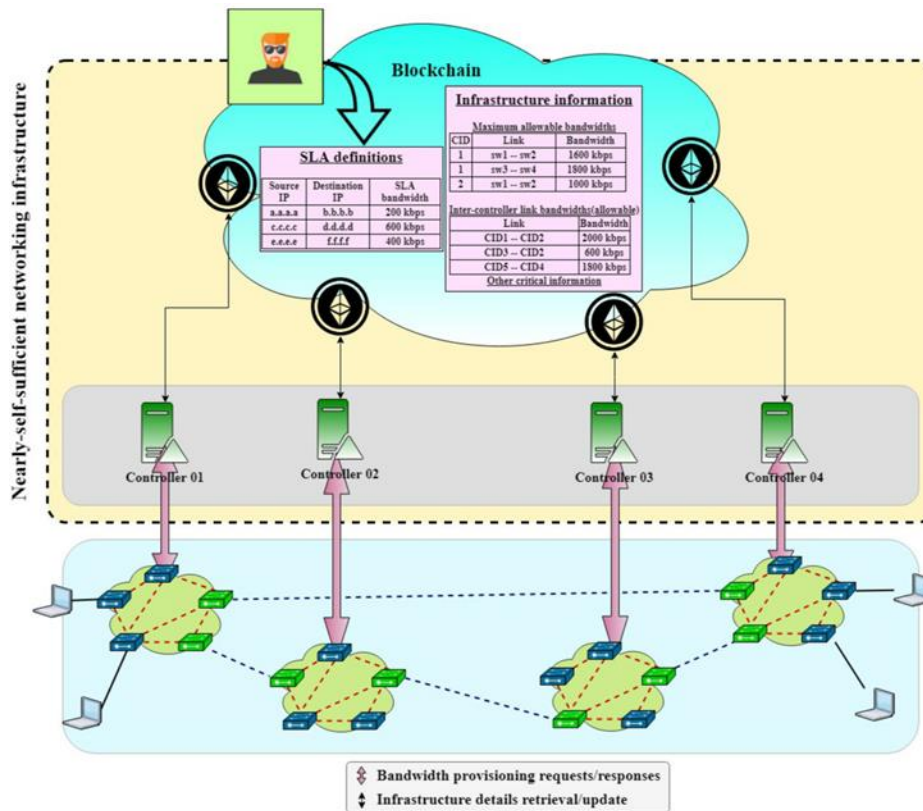

[03d7de0e6879ac27598642c35564f10d] was verified in 16.5540790558 seconds

Cross validating the received ARP reply

The screenshot shows a terminal window with a black background and white text. The first line is "Handling IP packet between 10.0.0.1 and 10.0.0.2". The second line is highlighted with a red box and has a red arrow pointing to it from a white box on the right that says "Cross validating the received ARP reply".

# Our Proposed Networking Solution with Case Studies

- In our ongoing work, we are exploiting the immutability and the turing completeness of the blockchain to enable network automation.

- Autonomous detection of malicious hosts.
  - ✓ To improve security (authorization)
- Autonomous bandwidth provisioning.
  - ✓ To improve responsiveness and reliability

Fig.9: High-level overview of network automation.

# Autonomous Malicious-Host Detection Mechanism

- The authorization of the host sending ARP requests/replies is verified via blockchain smart contract.
  - It is assumed that every valid host acquires an IP address using Dynamic Host Configuration Protocol (DHCP) at the SDN controllers.
  - Once the IP is assigned, the corresponding host's IP-MAC association is recorded in the blockchain platform.

Host IP	MAC address
20.0.0.1	48-2C-6A-1E-59-3D
20.0.0.5	48-2C-6A-1D-5C-ED
20.0.0.9	48-2C-6A-1E-23-4A

- The establishment of the end-to-end IP association without a qualified ARP request-reply pair is prevented.

# Autonomous Malicious-Host Detection Mechanism

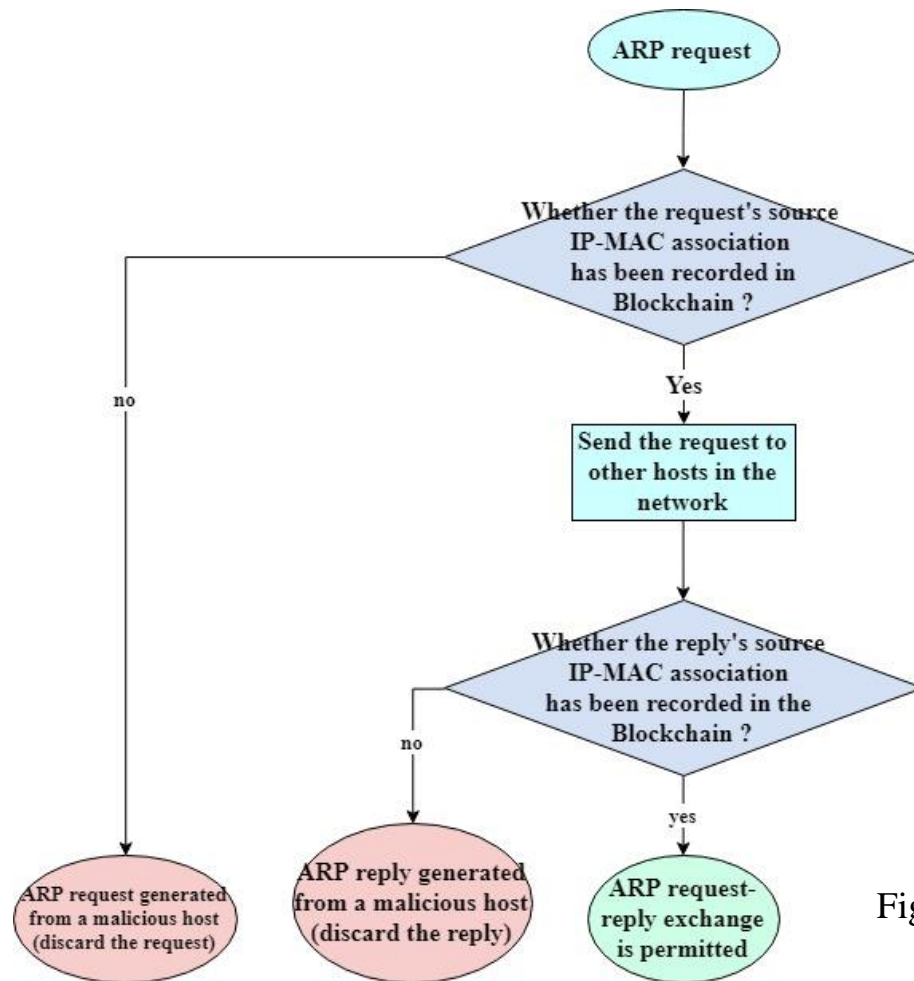

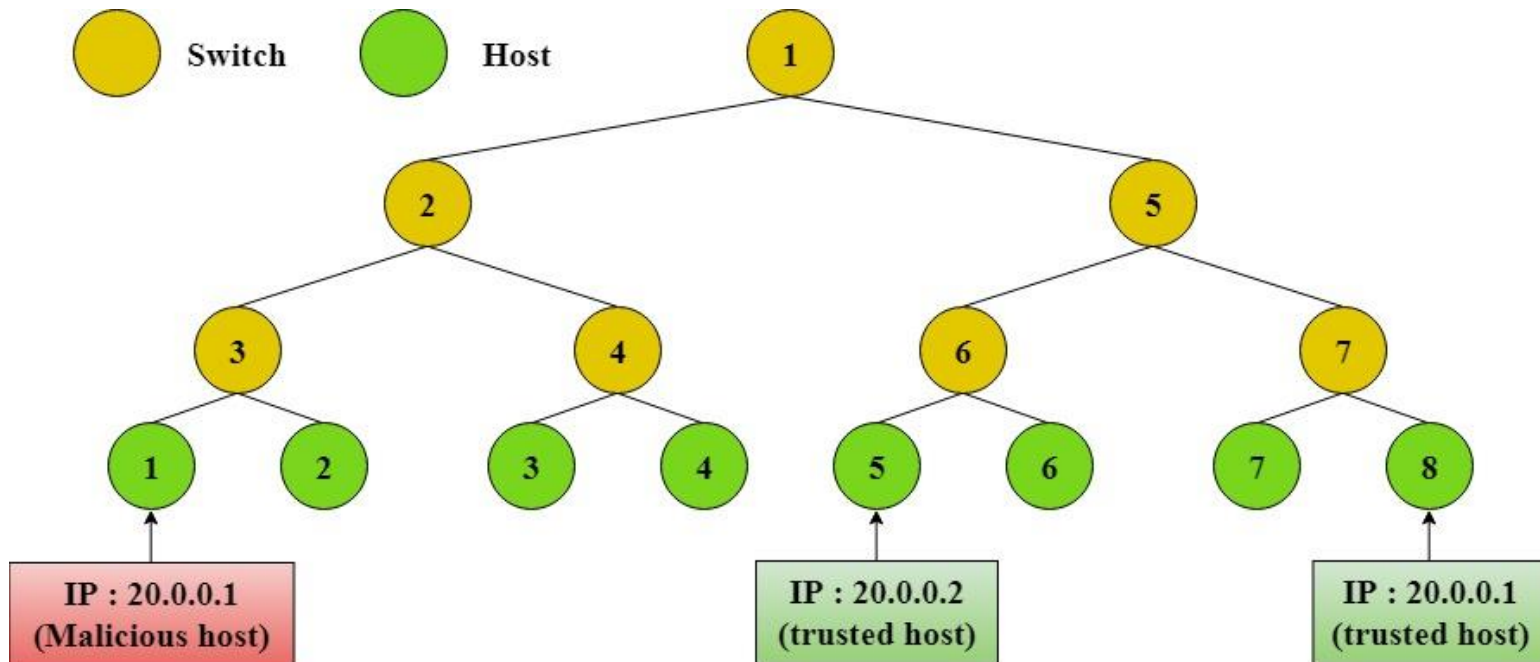

Fig.10: Flow chart for autonomous detection of malicious hosts.

# Autonomous Malicious-Host Detection Mechanism

## Case Studies

- The SDN network is assumed to have depth = 3 and fan-out = 2.
  - Initially, all the hosts have the IP addresses of the IPV4 range 20.0.0.0/24.

# Autonomous Malicious-Host Detection Mechanism

## Case Studies

- Host 8 with IP address 20.0.0.1 and Host 5 with IP address 20.0.0.2 are configured by using DHCP.
- Since both Hosts 5 and 8 get the IPs via DHCP, their corresponding IP-MAC associations are recorded in the blockchain.
  - These two hosts are identified as trusted hosts.

```
Host 20.0.0.2 has a valid MAC address association
Handling ARP packet: 20.0.0.2 requests the MAC of 20.0.0.1
Flooding initial ARP request on all switch edges
```

The authorization of Host 5 sending ARP request is verified at the controller via smart contract.

# Autonomous Malicious-Host Detection Mechanism

## Case Studies

- Host 8 with IP address 20.0.0.1 and Host 5 with IP address 20.0.0.2 are configured by using DHCP.
- Since both Hosts 5 and 8 get the IPs via DHCP, their corresponding IP-MAC associations are recorded in the blockchain
  - These two hosts are identified as trusted hosts.

```
Host 20.0.0.1 has a valid MAC address association
```

```
Handling ARP reply: 20.0.0.1 responds to 20.0.0.2
```

```
Sending the ARP reply to : 20.0.0.2
```

```
Host 20.0.0.1 has a invalid MAC address association...ARP reply will be discarded
```

```
Handling IP packet between 20.0.0.2 and 20.0.0.1
```

→ The authorization of Host 8 sending ARP reply is verified via smart contract.

→ Malicious host (Host 1) sending ARP reply is detected at the controller. The associated ARP reply is discarded.

# Autonomous Bandwidth Provisioning Mechanism

- Blockchain is used here to implement the following.
  - ✓ To impose SLAs (Service Level Agreements) into the networking logic
  - ✓ To keep track of available bandwidths of each links
- The metering and queue functionality of the OpenFlow Switch Specification has been used.
- A certain traffic flow can be categorized into two categories.
  - ✓ Guaranteed traffic(flag = 1)
  - ✓ Best-effort traffic(flag = 0)

Source IP	Destination IP	SLA BW	Flag
a.a.a.a	b.b.b.b	1Mbps	1
c.c.c.c	d.d.d.d	2Mbps	1
e.e.e.e	f.f.f.f	N/A	0

# Autonomous Bandwidth Provisioning Mechanism

- Three critical data-structures are defined via the blockchain smart contract.
  - Inter-controller link bandwidth matrix
    - ✓ To record all the links connecting controllers and their associated bandwidths

Controller pair	Bandwidth
(Controller 01 , Controller 02)	2000 kbps
(Controller 02 , Controller 03)	1800 kbps

- Controller link-bandwidth matrix
  - ✓ To record the link bandwidths of the individual controllers

Controller ID	link	Bandwidth
01	(2,3)	2000 kbps
02	(6,8)	400 kbps

# Autonomous Bandwidth Provisioning Mechanism

- Three critical data-structures are defined via the blockchain smart contract.
  - Traversal edge-switch matrix
    - ✓ To record the corresponding edge-switch when traversing from one controller to another.

Traversing controllers	Edge-switch datapath-ID (DPID)
(Controller 01 , Controller 02)	01
(Controller 02 , Controller 01)	02
(Controller 02 , Controller 03)	03

# Autonomous Bandwidth Provisioning Mechanism

- *Inter-controller link bandwidth matrix* and *controller link bandwidth matrix* are used to
  - Track of all the unallocated bandwidths throughout the network
  - Make decision on the bandwidth provisioning for a given source and destination.
- *Traversal edge-switch matrix* is used to
  - Find the two domain-edge switches of the domain of each controller that participates in the packet switching process for a certain source and destination.
  - The result from the above process is fed to individual controller to achieve the shortest path locally.

# Autonomous Bandwidth Provisioning Mechanism

## Case Studies

- Leveraging blockchain to identify different traffic types.
  - In our mechanism, the type and suitable bandwidth requirements of each flow is identified based on the entries located in the blockchain platform.

Source IP	Destination IP	Service Level Agreement (SLA) BW	Flag
10.0.0.1	10.0.0.5	N/A	0
10.0.0.2	10.0.0.6	N/A	0
10.0.0.3	10.0.0.7	2Mbps	1
10.0.0.4	10.0.0.8	3Mbps	1

# Autonomous Bandwidth Provisioning Mechanism

## Case Studies

- Leveraging blockchain to identify different traffic types.
  - In our mechanism, the type and suitable bandwidth requirements of each flow is identified based on the entries located in the blockchain platform.

A flow is identified as a best-effort flow

```
Requesting traffic type of the flow between : 10.0.0.1 <--> 10.0.0.5
```

```
Flag : 0 | Defined SLA : 0 Mbps | This is Best-Effort flow...!!!
```

```
Handling ARP packet: 10.0.0.3 requests the MAC of 10.0.0.7
```

```
Flooding initial ARP request on all switch edges
```

```
Handling ARP reply: 10.0.0.7 responds to 10.0.0.3
```

```
Sending the ARP reply to : 10.0.0.3
```

```
Handling IP packet between 10.0.0.3 and 10.0.0.7
```

A flow is identified as a guaranteed flow

```
Requesting traffic type of the flow between : 10.0.0.3 <--> 10.0.0.7
```

```
Flag : 1 | Defined SLA : 2 Mbps | This is Guaranteed flow...!!!
```

# Autonomous Bandwidth Provisioning Mechanism

## Case Studies

- Leveraging blockchain to keep the online track of all the available bandwidths.
  - When a request comes from a guaranteed flow, via smart contract the controller will automatically
    - ✓ Check all the available bandwidths throughout the shortest path from source to destination
    - ✓ Make a decision on whether a flow can be allocated.

```
Requesting traffic type of the flow between : 10.0.0.3 <--> 10.0.0.7
```

SLA is 2 Mbps

```
Flag : 1 | Defined SLA : 2 Mbps | This is Guaranteed flow...!!!
```

Minimum of  
available BWs along  
the path is 1 Mbps

```
Available bandwidths in the path : [1000, 1000]
```

```
Path installation NEGATIVE...!!! | End-to-end bandwidth provisioning failed...!!!
```

Bandwidth provisioning fails

# Autonomous Bandwidth Provisioning Mechanism

## Case Studies

- Leveraging blockchain to keep the online track of all the available bandwidths.
  - When a request comes from a guaranteed flow, via smart contract the controller will automatically
    - ✓ Check all the available bandwidths throughout the shortest path from source to destination
    - ✓ Make a decision on whether a flow can be allocated.

```
Requesting traffic type of the flow between : 10.0.0.3 <--> 10.0.0.7
```

```
Flag : 1 | Defined SLA : 2 Mbps | This is Guaranteed flow...!!!
```

```
Available bandwidths in the path : [5000, 5000]
```

```
Path installation POSITIVE...!!! | End-to-end bandwidth provisioning successful...!!!
```

SLA is 2 Mbps

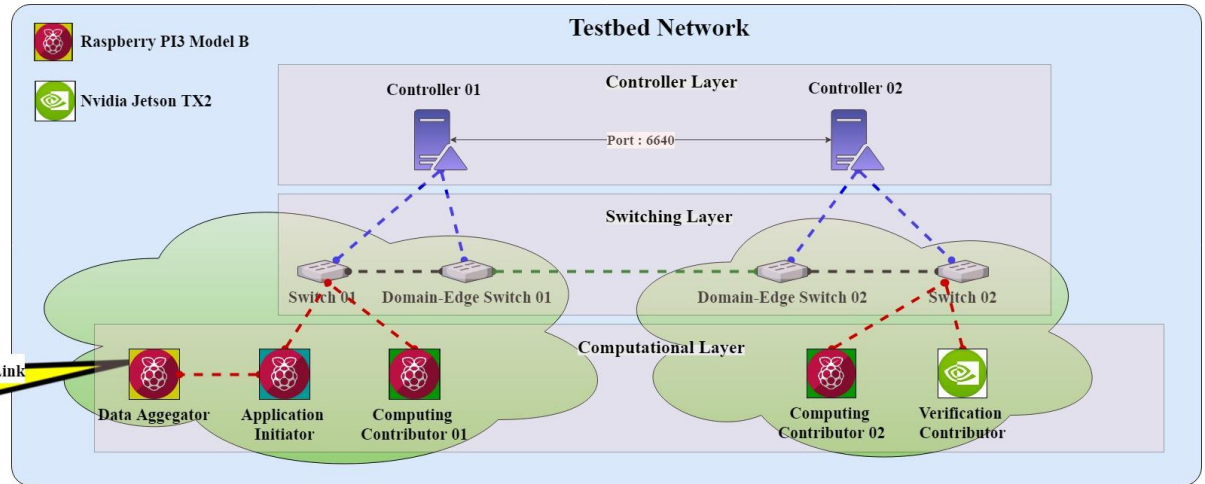

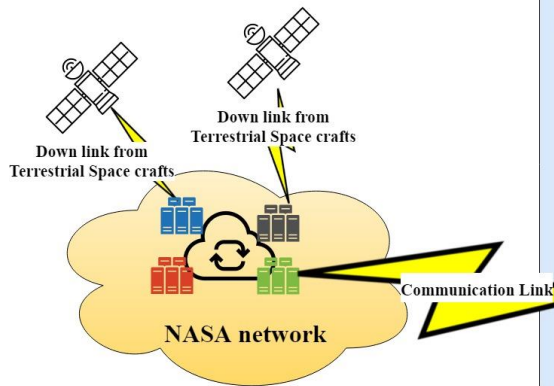

Minimum of available BWs along the path is 5 Mbps

Bandwidth provisioning succeeds

# Conclusions

- We develop a blockchain-enabled multi-controller SDN-based resilient networking management mechanism

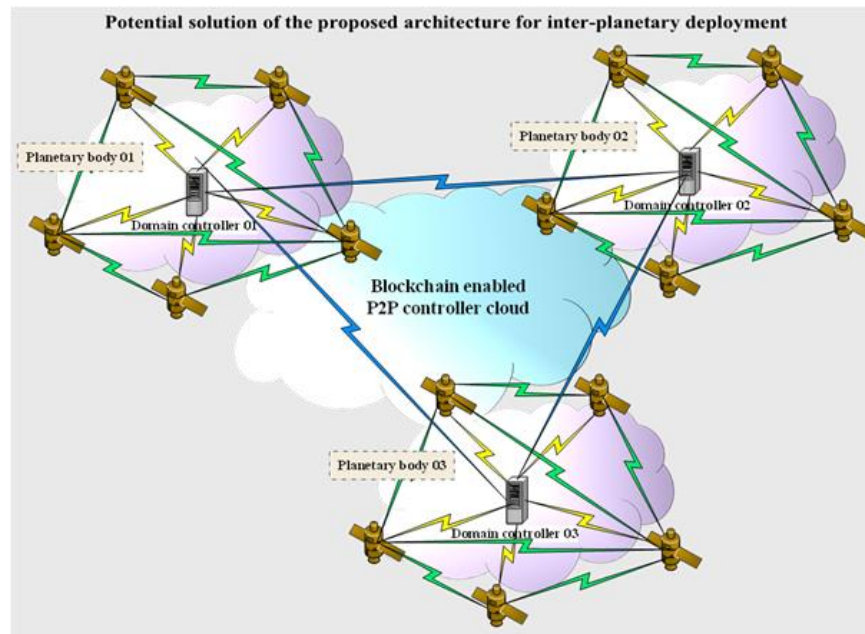

- This is part of the work for the NASA ECF Project “RNCP: A Resilient Networking and Computing Paradigm for NASA Space Exploration”.
  - NASA Research Collaborator: Mr. Rigoberto Roche in NASA Glenn Research Center

# Conclusions

- Applications
  - Deployment as a means of enabling intelligent and secure deep space communication networks

# Conclusions

- Applications
  - Deployment as a means of establishing emergency response networks in a disaster situation
